Digital communication and control systems, such as networks of communication devices, generally use digital switches to transfer signals between various components of the digital communication and control systems. The digital switches used in such a digital communication and control system may typically be arranged into layers, where the layers are connected by a series of physical links or links. The layers may comprise one or more network protocol layers, for example, where each network protocol layer may provide the functionality of a protocol layer in a corresponding upper layer. The corresponding upper layers may be known by those skilled in the art as Physical, Data Link, Network, Transport and Application layers. The Physical layer may provide functions for the transmission and reception of electrical signals via a physical link. The Physical layer may provide protocol functions to enable the link to behave as a network link. The Data Link layer may provide protocol functions for error control and frame format as appropriate for the type of physical link being used. The Network layer provides functions for forwarding the data frames on the network and may handle lower level data link protocol such as IEEE 802.3 at Ethernet speeds. The Transport layer handles end-to-end data transfer, including flow control, error checking, segmentation and reassembly, multiplexing, and demultiplexing functions. The Application layer provides the upper layer application protocols to a network user, for example, file transfers, remote terminal access to an information network and electronic mail. As data rates increase, a digital switch is used in a communications system to switch data, such as a data flow, between components in the communications system. A gigabit digital switch used for switching data may be connected to external line cards via one or more line cards, where each line
